Convolutional neural networks

- Convolutional neural network:
 - Used for image analysis
 - Uses convolutional layers followed by non-linearity functions and sub-sampling (pooling) layers.
 - Multi-layer perceptron at the end if regression or classification task

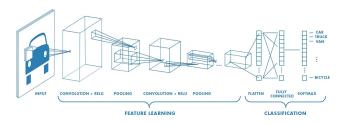

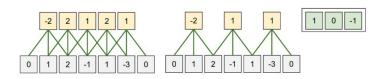

Table of Contents

- Convolution

1-D Convolution operation

$$out1D(x,y) = \sum_{i=-n}^{n} K(i+n+1)in(x+i)+b, \quad Kernel \in \mathbb{R}^{2n+1}, \ b \in \mathbb{R}$$

Parameters1:

- W length of input; 2n + 1 kernel size
- P amount of padding (to increase dimensionality)
- Type of padding (valid[absent], zero, same [extend], mirror)
- S stride (offset of kernel); D dilation (offset inside kernel)

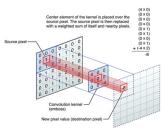

¹Depending on these parameters, what would be the size of output layer?

Predefined convolution examples

- $K = (\frac{1}{5}, \frac{1}{5}, \frac{1}{5}, \frac{1}{5}, \frac{1}{5})$ uniform averaging.
- K = (0.1, 0.2, 0.4, 0.2, 0.1) averaging with decaying weights.
- ullet K=(-1,0,+1) change detection $(f'pprox z_{t+1}-z_{t-1})$
- K = (+1, -2, +1) change of change detection $(f'' \approx (z_{t+1} z_t) (z_t z_{t-1}))$

2D convolution

2-D convolution

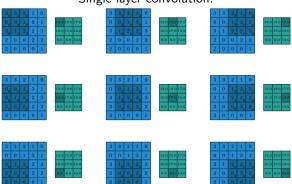

$$out2D(x, y) =$$

$$\sum_{i=-n}^{n} \sum_{i=-n}^{n} K(i+n+1,j+n+1) in(x+i,y+j) + b,$$

$$K \in \mathbb{R}^{(2n+1)x(2n+1)}, \ b \in \mathbb{R}$$

Convolution demo²

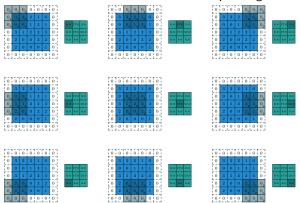

Single layer convolution:

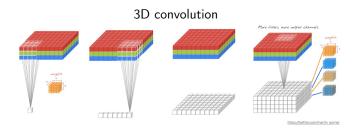

²Illustrations from Dumoulin et al. 2018.

Padding allows to increase output feature map

Convolution with stride and zero-padding:

3D convolution

$$out3D(x, y, c) = \sum_{i=-n}^{n} \sum_{j=-n}^{n} \sum_{c=1}^{C} K(i+n+1, j+n+1, c) in(x+i, y+j, c) + b,$$

$$K \in \mathbb{R}^{(2n+1)\times(2n+1)}, \ b \in \mathbb{R}$$

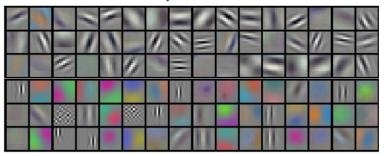

Convolution comments

Comments:

- #parameters\u00f3 because neuron is connected only to some neighborhood of input neurons
- #parameters↓ further, because we apply the same transformation in different locations
 - #parameters= $((2n+1)x(2n+1)C_{in}+1)C_{out}$ for set of C_{out} convolutions, applied to feature map with C_{in} channels.
- Visibility region of convolution output is $\pm n$ in terms of previous layer.
 - visibility region increases in terms of earlier layers.
- Stride>1 reduces output spatial dimensionality.
- Convolution should be followed by non-linear transformation.
- Typical to use pretrained convolutions from some large dataset (e.g. ImageNet)

Visualized convolutions from 1st layer of AlexNet

1st layer of AlexNet

- 1st layer convolution kernels $\in \mathbb{R}^{(2n+1)x(2n+1)x3}$, so can be visualized as images.
- Later convolutions use more channels, so they can be visualized by
 - taking actual patches, maximizing convolution activation
 - deriving patches giving maximal activation with

Convolution pyramid

- Convolution applied to input image extracts features.
- Convolution, applied to feature map (intermediate output) extracts more abstract features.
- Typical to gradually decrease spatial resolution, extracting more abstract features from wider areas of input image.
 - downsampling performed by strided convolutions or strided pooling layers.

Convolution pyramid

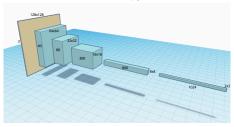

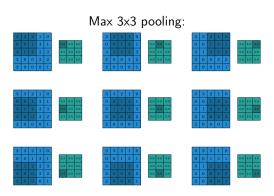

Table of Contents

- 1 Convolution
- 2 Pooling layer

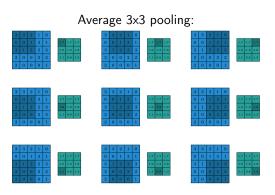

Max pooling

- Max pooling: "feature is present somewhere in the region" (e.g. for corner detector)
- Introduces invariance to small transitions on the image.
- Stride>1 reduces output spatial dimensionality.

Average pooling

- Avg. pooling: "average feature presence", e.g. for isolated point detector.
- Introduces invariance to small transitions on the image.
- Stride>1 reduces output spatial dimensionality.

Upscaling

- Output size can be increased by applying convolution to enlarged input
 - transposed convolution (padding input values, "bed of nails")

$$\left(\begin{array}{cccc} a & b \\ c & d \end{array}\right) \longrightarrow \left(\begin{array}{ccccc} 0 & 0 & 0 & 0 & 0 \\ 0 & a & 0 & b & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & c & 0 & d & 0 \\ 0 & 0 & 0 & 0 & 0 \end{array}\right)$$

• simple scaling (nearest neighbours or rescaling with smoothing)

$$\left(\begin{array}{ccc} a & b \\ c & d \end{array}\right) \longrightarrow \left(\begin{array}{cccc} a & a & b & b \\ a & a & b & b \\ c & c & d & d \\ c & c & d & d \end{array}\right)$$

Intermediary tensor->vector of fixed size

- Typical to use multi-layer perceptron at the end.
- It requires input of fixed size, whereas input image may be of various shapes.
- Solutions:
 - rescale&crop input image to fixed size
 - perform global channel-wise pooling $\mathbb{R}^{CxWxH} \to \mathbb{R}^C$
 - pyramid pooling:
 - split output into fixed grid mxm.
 - perform channel-wise pooling for each fragment selected by the grid
 - **3** stack results, so $\mathbb{R}^{C \times W \times H} \to \mathbb{R}^{Cm^2}$

Conclusion

- Fully-connected layers have too many parameters.
- Convolutions solve this by:
 - taking dependencies only from small neighborhood
 - applying the same transformation to different locations
- Avg. and max pooling implement invariance to small transitions on the image.
- Subsequent convolutions extract more abstract features from wider area of input image.
